Change Detection Methods Developed at the Canada Centre for Remote Sensing

- 1. Spectral change detection and change type identification:**
 - a. Change metric fusion (ChangeSat, R. Fraser);**
 - b. Cross correlation (C. Butson);**
 - c. Change vector analysis (R. Latifovic).**
- 2. Signature extension and post classification comparison (I. Olthof).**
- 3. Combined 1 & 2, landcover reclassification in change areas using constrained signature extension (R. Latifovic & D. Pouliot).**

Prince Albert National Park (PANP)

Common tree species:

- Trembling aspen;
- Balsam poplar;
- White spruce;
- Black spruce;
- Balsam fir.

Signature Extension Methodology

Implementation:

1. Theil-Sen/VGT normalized imagery generated for 1985, 1990, 1995, and 2000;
2. 1995 landcover generated using the Enhanced Classification Method;
3. Class spectral statistics extracted from baseline 1995 landcover map;
4. 1985, 1990, and 2000 classifications produced using 1995 class statistics with the minimum distance classifier;
5. Change identified by comparing maps between years.

At a thematic resolution of 2 classes (forest/non-forest) average map agreement between years was ~ 90 %. Assuming actual change between years was ~ 5 %, suggests ~ 5 % change error.

Signature Extension Results:

Harvesting and Regeneration

Evergreen closed tree canopy
Deciduous closed tree canopy
Mixed closed tree canopy
Mixed deciduous closed tree canopy
Evergreen open tree canopy w/ moss-shrub
Evergreen open tree canopy w/ shrub-moss
Low regen. To young broadleaf cover
Mixed evergreen deciduous open tree canopy
Mixed deciduous open tree canopy
Low regen. To young mixed cover
Deciduous shrubland
Grassland, prairie region
Wetlands
Temperate grassland sparse coniferous
High biomass crops and grasses
Medium biomass crops and grasses
Low biomass crops and grasses
Low vegetation cover, rock outcrops
Recent burns
Mostly bare disturbed areas
Low vegetation cover after disturbance

Signature Extension Results:

Water Table Changes

-  Water 2000
-  Dried between 1995 - 2000
-  Dried between 1990 - 1995
-  Dried between 1985 - 1990

Lakes are shrinking over time, perhaps caused by drought in the region over the past 20 years. Lakes shrink more in the prairies than in the shield just north, likely due to the fact that prairie lakes are shallower.

Signature Extension Results:

Water Table Changes

Fluctuations in water table drastically alter spectral properties of wetland areas and \therefore the identified landcover classes.

Signature Extension Results:

Defoliation

Defoliation survey for park in 2000 from Saskatchewan Environment and Resource Management.

Defoliation appears dark purple with SWIR, NIR, RED displayed as R, G, B.

Clusters defined as defoliation are shown in yellow.

Signature Extension Results:

Defoliation

Defoliation signatures were extend backward in time from 2000 to identify the potential past distribution.

Fragmentation Assessment

FRAGSTATS used to evaluate several simple fragmentation metrics:

- Percent area
- Patch density
- Edge density
- Mean perimeter to area ratio
- Percentage of like adjacencies

Statistics calculated for 3 landscape extents at 30 m and 90 m resolutions using forest/non-forest landscape model:

1. Park (**least fragmented**)
2. Park+greater park ecosystem (GPE)
3. GPE – Agriculture belt to the south (**most fragmented**)

Fragmentation Results:

Percent Forest Area

30 m Resolution

90 m Resolution

- ◆ Park (least fragmented)
- Park+GPE
- ▲ GPE-Agriculture (most fragmented)

Fragmentation Results:

Patch Density

30 m Resolution

90 m Resolution

- ◆ Park (least fragmented)
- Park+GPE
- ▲ GPE-Agriculture (most fragmented)

Fragmentation Results:

Edge Density

30 m Resolution

90 m Resolution

- ◆ Park (least fragmented)
- Park+GPE
- ▲ GPE-Agriculture (most fragmented)

Fragmentation Results:

Mean Perimeter to Area Ratio

30 m Resolution

90 m Resolution

- ◆ Park (least fragmented)
- Park+GPE
- ▲ GPE-Agriculture (most fragmented)

Fragmentation Results:

Percentage of Like Adjacencies

30 m Resolution

90 m Resolution

- ◆ Park (least fragmented)
- Park+GPE
- ▲ GPE-Agriculture (most fragmented)

Conclusions

- **Meaningful fragmentation indices were observed at 90 m resolution.**
- **Fragmentation results were highly sensitive to noise.**
- **Need to develop and evaluate a change\classification updating methodology that maintains a high degree of consistency over time.**
- **Need to include roads in the analysis from existing GIS and manual updating.**
- **Need to evaluate results for other more complex landscape models.**
- **Validation data required for more meaningful evaluations.**
